

Figure 12 Diffusion of A through stagnant, nondiffusing B: (a) benzene evaporating into air, (b) ammonia in air being absorbed into water.

One example, shown in Fig. 12(a), is in the evaporation of pure liquid such as benzene ( $A$ ) at the bottom of a narrow tube, where a large amount of inert or nondiffusing air ( $B$ ) is passed over the top.
$>$ The benzene vapor $(A)$ diffuses through the air $(B)$ in the tube. The boundary at the liquid surface at point 1 is impermeable to air, since air is insoluble in benzene liquid.
$>$ Hence, air (B) cannot diffuse into or away from the surface. At point 2 the partial pressure $P_{A 2}=0$, since a large volume of air is passing by.
> Another example, shown in Fig. 12(b), occurs in the absorption of $\mathrm{NH}_{3}(A)$ vapor which is in air (B) by water.
> The water surface is impermeable to the air, since air is only very slightly soluble in water. Thus, since B cannot diffuse, $\boldsymbol{N}_{B}=0$.
> To derive the case for $A$ diffusing in stagnant, nondiffusing $B, N_{B}=0$ is substituted into the general equation (24)

$$
\begin{equation*}
N_{\mathrm{A}}=-c D_{A B} \frac{\mathrm{~d} x_{A}}{\mathrm{~d} z}+\frac{c_{A}}{c}\left(N_{A}+0\right) \tag{38}
\end{equation*}
$$

$>$ The convective flux of $A$ is $\left(c_{A} / c\right)\left(N_{A}+0\right)$. Keeping the total pressure $P$ constant, substituting $c=P / R T, p_{A}=$ $x_{A} P$, and $c_{A} / c=p_{A} / P$ into the above equation

$$
\begin{equation*}
N_{A}=-\frac{D_{A B}}{R T} \frac{d p_{A}}{d z}+\frac{p_{A}}{P} N_{A} \tag{39}
\end{equation*}
$$

> Rearranging and integrating,

$$
\begin{align*}
& N_{A}\left(1-\frac{p_{A}}{P}\right)=-\frac{D_{A B}}{R T} \frac{d p_{A}}{d z}  \tag{40}\\
& N_{A} \int_{z_{l}}^{z_{2}} d z=-\frac{D_{A B}}{R T} \int_{p_{A l}}^{p_{A 2}} \frac{d p_{A}}{\left(1-p_{A} / P\right)}  \tag{41}\\
& N_{A}=\frac{D_{A B} P}{R T\left(z_{2}-z_{l}\right)} \ln \left(\frac{P-p_{A 2}}{P-p_{A l}}\right) \tag{42}
\end{align*}
$$

> The above equation is the final equation to be used to calculate the flux of $A$.
$>$ However, it is often written in another form.
$>A$ log mean value of the inert $B$ is defined as follows.
$>$ Since $P=p_{A 1}+p_{B 1}=p_{A 2}+p_{B 2}, p_{B 1}=P-p_{A 1}$ and $p_{B 2}=P-p_{A 2}$

$$
\begin{equation*}
P_{B M}=\frac{p_{B 2}-p_{B 1}}{\ln \left(p_{B 2} / p_{B 1}\right)}=\frac{p_{A 1}-p_{A 2}}{\ln \left[\left(P-p_{A 2}\right) /\left(P-p_{A 1}\right)\right]} \tag{43}
\end{equation*}
$$

## Thus,

$$
\begin{equation*}
N_{A}=\frac{D_{A B} P}{R T\left(Z_{2}-Z_{1}\right) p_{B M}}\left(p_{A 1}-p_{A 2}\right) \tag{44}
\end{equation*}
$$

Compare with the earlier equation for equimolar counterdiffusion:

$$
J_{A}=\frac{D_{A B}\left(p_{A l}-p_{A 2}\right)}{R T\left(z_{2}-z_{1}\right)}
$$

Therefore, in the present case, $P / p_{B M}$ can be regarded as correction factor.

In addition, for gases, Eq. (20) $N_{A}=J_{A}+c_{A} v_{M}$ can also be expressed using mole fraction in vapor phase ( $y_{A}$ ), since:

$$
\begin{gather*}
\mathrm{c}_{\mathrm{A}}=\rho_{\mathrm{M}} \mathrm{y}_{\mathrm{A}}  \tag{45}\\
v_{\mathrm{M}}=\frac{N}{\rho_{\mathrm{M}}} \tag{46}
\end{gather*}
$$

where:
$\rho_{M}=$ molar density (kgmole/m ${ }^{3}$ )
$=1 / 22.41 \mathrm{kgmole} / \mathrm{m}^{3}$ (at standard conditions, $0^{\circ} \mathrm{C}$ \& 1 atm )
$y_{A}=$ mole fraction of component $A$ in vapor phase
$N$ = total convective flux of the whole stream relative to the stationary point (kgmole/m ${ }^{2}$.s)
$v_{M}=$ molar average velocity $\left(\mathrm{ms}^{-1}\right)$
$c_{A}=$ molar concentration of component $A\left(\mathrm{kgmole} / \mathrm{m}^{3}\right)$

Thus the Eq. (20) becomes:

$$
\begin{equation*}
N_{A}=y_{A} N-D_{A B} \rho_{M} \frac{d y_{A}}{d z} \tag{47}
\end{equation*}
$$

Since $N=N_{A}+N_{B}$, and when only component $A$ is being transferred (i.e.: $N_{B}=0$ ), the total flux to or away from the interface $\boldsymbol{N}$ is the same as $\boldsymbol{N}_{A}$, then the Eq. becomes:

$$
\begin{equation*}
N_{A}=y_{A} N_{A}-D_{A B} \rho_{M} \frac{d y_{A}}{d z} \tag{48}
\end{equation*}
$$

## Rearranging and integrating:

$$
\begin{gather*}
N_{A}\left(1-y_{A}\right)=-D_{A B} \rho_{M} \frac{d y_{A}}{d z} \\
N_{A} \int_{\mathrm{z}_{1}}^{z_{2}} d z=-D_{A B} \rho_{M} \int_{y_{A 1}}^{y_{A 2}} \frac{d y_{A}}{\left(1-y_{A}\right)}  \tag{50}\\
\mathrm{N}_{\mathrm{A}}=\frac{\mathrm{D}_{\mathrm{AB}} \rho_{\mathrm{M}}}{\mathrm{z}_{2}-\mathrm{z}_{1}} \ln \left(\frac{1-\mathrm{y}_{\mathrm{A} 2}}{1-\mathrm{y}_{\mathrm{A} 1}}\right) \tag{51}
\end{gather*}
$$

Similarly,

$$
\begin{aligned}
& y_{B 1}=1-y_{A 1} \\
& y_{B 2}=1-y_{A 2} \\
& y_{B 2}-y_{B 1}=y_{A 1}-y_{A 2} \text { and }\left(y_{A 1}-y_{A 2}\right) /\left(y_{B 2}-y_{B 1}\right)=1
\end{aligned}
$$

Then,

$$
\begin{equation*}
N_{A}=\frac{D_{A B} \rho_{M}}{z_{2}-z_{1}} \cdot \frac{y_{A I}-y_{A 2}}{y_{B 2}-y_{B 1}} \ln \left(\frac{y_{B 2}}{y_{B 1}}\right) \tag{52}
\end{equation*}
$$

The logarithmic mean of $y_{B 1}$ and $y_{B 2}$ is given by:

$$
\begin{equation*}
y_{B M}=\frac{y_{B 2}-y_{B I}}{\ln \left(y_{B 2} y_{B I}\right)} \tag{53}
\end{equation*}
$$

Finally, by substituting Eq. (53) into Eq. (52) gives:

$$
\begin{equation*}
N_{A}=\frac{D_{A B} \rho_{M}}{\left(z_{2}-z_{1}\right) y_{B M}}\left(y_{A 1}-y_{A 2}\right) \tag{54}
\end{equation*}
$$

Example:
Water in the bottom of a narrow metal tube is held at a constant temperature of 293 K . The total pressure of air (assume dry) is $1.01325 \times 10^{5} \mathrm{~Pa}(1.0 \mathrm{~atm})$ and the temperature is $293 \mathrm{~K}\left(20^{\circ} \mathrm{C}\right)$. Water evaporates and diffuses through the air in the tube and the diffusion path $z_{2}-z_{1}$ is $0.1524 \mathrm{~m}(0.5 \mathrm{ft})$ long. The diagram is similar to the shown figure. Calculate the rate of evaporation at steady state in $\mathrm{lb} \mathrm{mol} / \mathrm{ft}^{2} \cdot \mathrm{~h}$ and $\mathrm{kgmole} / \mathrm{m}^{2}$.s. The diffusivity of water vapor at 293 K and 1 atm pressure is $0.250 \times 10^{-4} \mathrm{~m}^{2} / \mathrm{s}$. Assume that the system is isothermal. Use SI and English units.

## Solutions

$>$ The diffusivity is converted to $\mathrm{ft}^{2} / \mathrm{h}$ by using the conversion factor (refer Appendix 1, McCabe, Smith and Harriott).

$$
D_{A B}=\left(0.250 \times 10^{-4}\right)\left(3.875 \times 10^{-4}\right)=0.969 \mathrm{ft}^{2} / \mathrm{h}
$$

> Using Appendix A. 2 (Christie John Geankoplis), the vapor pressure of water at $20^{\circ} \mathrm{C}$ is 17.54 mmHg

$$
\begin{aligned}
& p_{A l}=\frac{17.54}{760}=0.0231 \mathrm{~atm}=0.0231\left(1.01325 \times 10^{5}\right)=2.341 \times 10^{3} \mathrm{~Pa} \\
& p_{A 2}=0(\text { pure air })
\end{aligned}
$$

$T=460+68=528^{\circ} \mathrm{R}=293 \mathrm{~K}$
$R=82.057 \mathrm{~cm}^{3}$ atm $/ \mathrm{gmole} \cdot \mathrm{K}=0.730 \mathrm{ft}^{3} \cdot$ atm $/ \mathrm{lbmole} \cdot$ ${ }^{\circ}$ R
$>$ In order to calculate the value of $p_{B M}$ :

$$
\begin{aligned}
& p_{B 1}=P-p_{A 1}=1.00-0.0231=0.9769 \mathrm{~atm} \\
& p_{B 2}=P-p_{A 2}=1.00-0=1.00 \mathrm{~atm}
\end{aligned}
$$

> Therefore:

$$
p_{B M}=\frac{p_{B 2}-p_{B 1}}{\ln \left(p_{B 2} / p_{B 1}\right)}=\frac{1.00-0.9769}{\ln (1.00 / 0.9769)}=0.988 \mathrm{~atm}=1.001 \times 10^{5} \mathrm{~Pa}
$$

Since $p_{B 1}$ is close to $p_{B 2}$, the linear mean $\left(p_{B 1}+p_{B 2}\right) / 2$ could be used and would be very close to $p_{B M}$.

## Substituting in Eq. (44) with $z_{2}-z_{1}=0.5 \mathrm{ft}(0.1524 \mathrm{~m})$,

 thus:$$
\begin{aligned}
N_{A} & =\frac{D_{A B} P}{R T\left(z_{2}-z_{1}\right) p_{B M}}\left(p_{A 1}-p_{A 2}\right) \\
& \left.=\frac{0.969\left(\frac{f t^{2}}{h}\right)(1.0)(\mathrm{atm})(0.0231-0)(\mathrm{atm})}{0.730\left(\frac{\mathrm{ft}}{}{\mathrm{Ibmol} \cdot{ }^{3} R}^{0} \mathrm{~atm}\right.}\right)(528)\left({ }^{0} R\right)(0.5)(\mathrm{ft})(0.988)(\mathrm{atm}) \\
& =1.175 \times 10^{-4} \mathrm{lbmole} / f t^{2} \cdot \mathrm{~h}
\end{aligned}
$$

$$
\begin{aligned}
N_{A} & =\frac{D_{A B} P_{T}}{R T\left(z_{2}-z_{1}\right) p_{B M}}\left(p_{A l}-p_{A 2}\right) \\
& =\frac{\left(0.250 \times 10^{-4}\right)\left(\frac{\mathrm{m}^{2}}{s}\right)\left(1.01325 \times 10^{5}\right)(\mathrm{Pa})\left(2.341 \times 10^{3}-0\right)(\mathrm{Pa})}{8314\left(\frac{\mathrm{~m}^{3} \cdot \mathrm{~Pa}}{\mathrm{kgmol} \cdot \mathrm{~K}}\right)(293)(\mathrm{K})(0.1524)(\mathrm{m})\left(1.001 \times 10^{5}\right)(\mathrm{Pa})} \\
& =1.595 \times 10^{-7} \mathrm{kgmole} / \mathrm{m}^{2} \cdot \mathrm{~s}
\end{aligned}
$$

## Molecular Diffusion in Liquids

$>$ Diffusion of solutes in liquid is very important in many industrial processes especially in separation operations such as:

1) Gas absorption
2) Distillation
3) Liquid-liquid extraction or solvent extraction
> Rate of molecular diffusion in liquids is considerably slower than in gases.
$>$ The molecules in a liquid are very close together compared to a gas. Therefore, the molecules of the diffusing solute $A$ will collide with molecules of liquid $B$ more often and diffuse more slowly than in gases.
> For diffusion in liquids, an important difference from diffusion in gases is that the diffusivities are often dependent on the concentration of the diffusing components.
> Similar to those for gases, equations for diffusion in liquids can be classified in two cases:
4) Steady-state equimolar counterdiffusion,

Starting from general Eq. (24): $N_{A}=-c D_{A B} \frac{d x_{A}}{d z}+\frac{c_{A}}{c}\left(N_{A}+N_{B}\right)$ and knowing $N_{A}=-N_{B}$, then:

$$
\begin{equation*}
J_{A}=\frac{D_{A B} c_{a v}}{z_{T}}\left(x_{A i}-x_{A}\right)=\frac{D_{A B}}{z_{T}}\left(c_{A i}-c_{A}\right) \tag{55}
\end{equation*}
$$

Note that $\boldsymbol{c}_{\boldsymbol{T}}$ is consider as $\boldsymbol{c}_{\mathrm{av}}$
$c_{a v}$ is defined as follows:

$$
\begin{equation*}
c_{a v}=\left(\frac{\rho}{M}\right)_{a v}=\frac{\left(\frac{\rho_{1}}{M_{1}}+\frac{\rho_{2}}{M_{2}}\right)}{2} \tag{56}
\end{equation*}
$$

## where:

$c_{a v} \quad=$ average total concentration of $A+B\left(\mathrm{kgmole} / \mathrm{m}^{3}\right)$
$M_{1} \quad=$ average molecular weight of the solution at point 1 (kg mass/kgmole)
$\rho_{1} \quad=$ average density of the solution at point $1\left(\mathrm{~kg} / \mathrm{m}^{3}\right)$
2) Steady-state diffusion of $A$ through nondiffusing $B$

Since $N_{B}=0$, If Eq. (44) is rewritten in terms of concentrations by substituting, $c_{a v}=P / R T, c_{A 1}=$ $p_{A 1} / R T$, and $x_{B M}=p_{B M} / P$, we obtain the equation for liquids at steady state:

$$
\begin{equation*}
N_{A}=\frac{D_{A B} c_{a v}}{\left(z_{2}-z_{1}\right) x_{B M}}\left(x_{A l}-x_{A 2}\right) \tag{57}
\end{equation*}
$$

where

$$
\begin{equation*}
x_{B M}=\frac{x_{B 2}-x_{B 1}}{\ln \left(x_{B 2} / x_{B 1}\right)} \tag{58}
\end{equation*}
$$

Note that $x_{A 1}+x_{B 1}=x_{A 2}+x_{B 2}=1.0$. For dilute solution, $x_{B M}$ is close to 1.0 and $c$ is essentially constant. Then, the Eq.(57) simplifies to:

$$
\begin{equation*}
N_{A}=\frac{D_{A B}}{\left(z_{2}-z_{1}\right)}\left(c_{A 1}-c_{A 2}\right) \tag{59}
\end{equation*}
$$

## Example:

Calculate the rate of diffusion of acetic acid (A) across a film of nondiffusing water $(B)$ solution 1 mm thick at $17^{\circ} \mathrm{C}$ when the concentrations on opposite sides of the film are 9 and $3 \mathrm{wt} \%$, respectively. The diffusivity of acetic acid in the solution is $0.95 \times 10^{-9} \mathrm{~m}^{2} / \mathrm{s}$.

## Solution:

Given:
$\left(z_{2}-z_{1}\right)=0.001 \mathrm{~m}$
$M_{A}=60.03 \mathrm{~kg} / \mathrm{kmole}$
$M_{B}=18.02 \mathrm{~kg} / \mathrm{kmole}$
At $17^{\circ} \mathrm{C}$ : Density of the $9 \%$ solution $=1012 \mathrm{~kg} / \mathrm{m}^{3}$
Density of the $3 \%$ solution $=1003.2 \mathrm{~kg} / \mathrm{m}^{3}$

## Consider basis of solution $=1 \mathbf{k g}$,

## At point 1:

$x_{A 1}=\frac{0.09 / 60.03}{0.09 / 60.03+0.91 / 18.02}=\frac{0.0015}{0.0520}=0.0288$ mole fraction acetic acid
$x_{B 1}=1-0.0288=0.9712$ mole fraction water

Molecular weight of the solution, $M_{1}=\frac{1}{0.0520}=19.21 \mathrm{~kg} / \mathrm{kmole}$
$\frac{\rho_{1}}{M_{1}}=\frac{1012}{19.21}=52.7 \mathrm{kmole} / \mathrm{m}^{3}$

## Similarly, at point 2:

$x_{A 2}=\frac{0.03 / 60.03}{0.03 / 60.03+0.97 / 18.02}=\frac{0.0005}{0.0543}=0.0092$ mole fraction acetic acid
$x_{B 2}=1-0.0092=0.9908$ mole fraction water
Molecular weight of the solution, $M_{2}=\frac{1}{0.0543}=18.42 \mathrm{~kg} / \mathrm{kmole}$
$\frac{\rho_{2}}{M_{2}}=\frac{1003.2}{18.42}=54.5 \mathrm{kmole} / \mathrm{m}^{3}$
Then,

$$
\left(\frac{\rho}{M}\right)_{a v}=\frac{52.7+54.5}{2}=53.6 \mathrm{kmole} / \mathrm{m}^{3}
$$

$$
x_{B M}=\frac{x_{B 2}-x_{B 1}}{\ln \left(x_{B 2} / x_{B 1}\right)}=\frac{0.9908-0.9712}{\ln (0.99080 .9712)}=0.980
$$

Finally, substitute all known values in the Eq.:

$$
\begin{aligned}
N_{A} & =\frac{0.95 \times 10^{-9}\left(\frac{\mathrm{~m}^{2}}{s}\right)}{(0.001)(\mathrm{m})(0.980)}(53.6)\left(\frac{\mathrm{kmol}}{\mathrm{~m}^{3}}\right)(0.0288-0.0092) \\
& =1.018 \times 10^{-6} \mathrm{kmole} / \mathrm{m}^{2} \cdot \mathrm{~s}
\end{aligned}
$$
