ALMUSTAQBAL UNIVERSITY COLLEGE

Medical Labs Techniques Department

Stage: First year students

Subject : General chemistry 1 - Lecture 5

Lecturer: Assistant professor Dr. SADIQ . J. BAQIR

Expressing concentrations By Physical units:

A. Percent concentration (parts per hundred):

It can be expressed in several ways such as:

1 Weight percent (w/w)%

Weight percent(
$$\frac{w}{w}$$
)% = $\frac{weight \ of \ solute}{weight \ of \ solution}$ x 100 %

e.g: Nitric acid (70%) solution, means that it contains (70 gm) of HNO_3 for each (100 gm) of solution.

2)volume percent (V/V)%

Volume percent
$$(\frac{V}{V})\% = \frac{volume \ of \ solute}{volume \ of \ solution} \times 100\%$$

It is commonly used to specify the concentration of a solution prepared by diluting a pure liquid with another liquid.(e.g. perfumes)

e.g: 5% aqueous solution of a perfume usually describe a solution prepared by diluting 5 mL of perfume with enough water to give 100 mL.

3 weight/volume percent (w/V)%

weight/volume percent
$$(\frac{w}{V})\% = \frac{weight \ of \ solute(gm)}{volume \ of \ solution(mL)} \times 100\%$$

It is often employed to indicate the composition of dilute aqueous solution of solid dissolved in water. **e.g**: 5% aqueous potassium nitrate refers to a solution prepared by dissolving (5.0 gm) of KNO₃ in sufficient amount of water to give (100 mL) of solution .

Example:

Describe the preparation of one liter of (10%) NaCl solution $(\frac{w}{v})$ %.

Solution:

weight/volume percent
$$(\frac{w}{V})\% = \frac{weight \ of \ solute(gm)}{volume \ of \ solution(mL)} \times 100\%$$

$$10\% = \frac{weight \ of \ solute(gm)}{1000 \ mL} \times 100\%$$

Weight of solute (gm) =
$$\frac{10 \times 1000}{100}$$
 = 100 g

Then (100gm) of NaCl is to be dissolved in asufficient volume of water and the volume is to be completed to (1) liter to get 10% solution of NaCl.

Example

Prepare a 20 mL of 5% KCl solution from pure solid KCl

Solution

weight/volume percent (
$$\frac{w}{V}$$
)% = $\frac{weight\ of\ solute(gm)}{volume\ of\ solution(mL)}$ x 100%

$$5\% = \frac{weight\ of\ solute(gm)}{20mL} \times 100\%$$

Weight of solute, KCl (gm) =
$$\frac{5 \times 20}{100}$$
 = 1 gm

Then 1 gm of KCl is to be dissolved in water and the volume is to be completed to 20 mL.

Example:

Calculate the $\left(\frac{w}{v}\right)$ % concentration of the aqueous solution of sodium chloride prepared by dissolving 5g of NaCl in water and completing the volume to 250 mL.

Answer:

$$\left(\frac{w}{v}\right)\% = \frac{weight\ of\ solute(gm)}{volume\ of\ solution(mL)}\ x\ 100\%$$

$$\left(\frac{w}{v}\right)\% = \frac{5 gm}{250 mL} \times 100\% = 2 \%$$

ملاحظه

نلاحظ ان هذا النوع من التراكيز ليس له علاقه بالكتله الموليه للماده المطلوب تحضير محلول منها والشرط المهم هنا ان تكون الماده المذابه (solute) تامة الذوبان في المحلول المحضر فيمكن ان ياتي في السؤال اي نوع ماده (مثلا Nacl, KCl, KCl), المحضر فيمكن الحل للسؤال بنفس الطريقه لكل المواد اي لايؤثر اسم الماده في الحل .

Conversion to molarity:

Molarity (M) =
$$\frac{\left(\frac{w}{v}\right)\% \times 10}{M.wt}$$

Example:

Calculate the Molarity of the solution that is 20(w/v)% of KCl (74.5gm/mol)?

solution:

Molarity(M) =
$$\frac{\left(\frac{W}{V}\right)\% x10}{M. wt}$$

Molarity(M) =
$$\frac{20 \times 10}{74.5}$$
 = 2.68 M

طريقه ثانيه للحل

Checking by using
$$Molarity(M) = \frac{wt_{gm}}{M.wt} x \frac{1000}{V_{ml}}$$

Molarity(M) =
$$\frac{20_{gm}}{74.5} \times \frac{1000}{100_{mL}} = 2.68 \text{ M}$$

B. Part per million (ppm) and part per billion (ppb):

It is a convenient way to express the concentration of the very dilute solution (by ppm or ppb).

$$(1~ppm = 1mg~/~liter)~~or~~~(1ppm = 1\mu g~/mL)$$

ppm: is a mass ratio of grams of solute to one million grams of sample or solution.

$$C_{ppm} = \frac{mass\ of\ solute(gm)}{mass\ of\ solution\ (gm)}\ x\ 10^6$$

ppb: is a mass ratio of grams of solute to one billion grams of sample or solution .

$$C_{ppb} = \frac{mass\ of\ solute(gm)}{mass\ of\ solution\ (gm)} \times 10^9$$

also

$$Cppm = \frac{mass \ of \ solute(mg)}{volume \ of \ solution(liter)}$$

$$\mathbf{Cppm} = \frac{wt(mg)}{V(liter)} = \frac{\frac{wt(\mu g)}{1000}}{\frac{VmL}{1000}}$$

Cppm =
$$\frac{wt(\mu g)}{VmL}$$
 ($\mu g / mL$)

$$1~gm=1000~mg~~,~~1mg=1000~\mu g~,$$

$$1gm = 10^6 \mu g$$
 , $1gm = 10^9 ng$

Cppm =
$$\frac{wt(gm)}{VmL} \times 10^6$$

Example: Prepare (500mL) of (1000 ppm) KCl aqueous solution.

solution:

Cppm =
$$\frac{wt(gm)}{VmL} \times 10^6$$

$$wt_{gm} = \frac{C_{ppm} \, x \, V_{mL}}{10^6}$$

wt(gm) =
$$\frac{1000 \times 500}{10^6}$$
 = 0.5 gm

Then $0.5~\rm gm$ of KCl is to be dissolved in water and the volume is completed to $500~\rm mL$ in a volumetric flask to get($1000~\rm ppm$) solution.

Relationship of ppm with Molarity(M) and Normality (N)

Molarity(M) =
$$\frac{PPm}{Mwt x 1000}$$
 یستخدم هذا القانون لتحویل الترکیز من PPm الی المولاریه (M) یستخدم هذا القانون لتحویل الترکیز من $\frac{PPm}{Eq.wt x 1000}$ یستخدم هذا القانون لتحویل الترکیز من PPm الی الترکیز النورمالی (N)

Example: Calculate the molarity of K^+ (39.1 g/mol) for the K_3 Fe(CN)₆ aqueous solution of (63.3 ppm) concentration?

Solution:

$$K_3Fe(CN)_6$$
 \longrightarrow $3K^+ + Fe(CN)_6^{3-1}$ \longrightarrow $3mole$

63.3ppm
$$k_3 Fe(CN)_6 \rightarrow 3x 63.3ppm K^+ = 189.9 ppm K+$$

Molarity(M) =
$$\frac{PPm}{Mwt \ x1000} = \frac{189.9PPm}{39.1 \ x1000} = 4.86 \ x \ 10^{-3} M$$
 (molarity of K⁺)

$$M_{k+} = 4.86 \times 10^{-3} M$$

Example:

The maximum allowed concentration of chloride in drinking water supply is $(2.50 \times 10^2 \text{ ppm})$. express this concentration in terms of mole/liter (M)?

Solution:

$$ppm = mg/L$$

$$Molarity(M) = \frac{PPm}{Mwt \, x1000}$$

$$Molarity(M) = \frac{PPm}{Mwt \, x1000} = \frac{2.5 \, x \, 10^2}{35.5 \, x \, 1000} = 7.05 \, x \, 10^{-3} \, M$$

Second method:

$$2.5 x 10^{2} ppm = \frac{2.5 x 10^{2} mg}{liter}$$

Molarity (M) =
$$\frac{\text{wt}_{\text{gm}}}{\text{M. wt } x \text{ V}_{\text{L}}}$$

Molarity(M) =
$$\frac{(2.5 \times 10^2 \times 10^{-3})\text{gm}}{35.5 \times 1}$$

$$M = 7.05 \times 10^{-3} M$$

P- fuctions:

$$pX = -log[X]$$

Examples:

$$pH = -log[H3O+]$$

$$[H3O+] = 10-pH$$

$$pOH = -log[OH-]$$

$$[OH-] = 10-pOH$$

$$pNa = -log[Na+]$$

$$pCl = -log[Cl-]$$

Example:

Calculate the P-value of each ion in 1.76×10^{-3} M aqueous solution of Na_3PO_4 .

Solution:

Na₃PO₄
$$\longrightarrow$$
 3Na⁺ + PO₄³⁻

1 mole 3 mole 1 mole

1.76x10⁻³ 3 (1.76x10⁻³) 1.76x10⁻³

[Na⁺] = 3 x 1.76 x 10⁻³ = 5.28 x 10⁻³ M

pNa⁺ = $-\log [5.28 \times 10^{-3}] = 2.277$

p(PO₄³⁻)= $-\log [1.76 \times 10^{-3}] = 2.754$

Note:

in case of $Na_2CO_3 \rightarrow 2Na^+ + CO_3^{\ 2^-}$ or $K_2CO_3 \rightarrow 2K^+ + CO_3^{\ 2^-}$ $NaCl \rightarrow Na^+ + Cl^-$ or $KCl \rightarrow K^+ + Cl^-$
