Example (2): In an internal combustion engine, during the compression stroke the heat rejected to the cooling water is $(50 \mathrm{~kJ} / \mathrm{kg})$ and the work input is $(100 \mathrm{~kJ} / \mathrm{kg})$. Calculate the change in internal energy of the working fluid stating whether it is a gain or loss.

## Solution:

$q-w=\Delta u$
Since heat is rejected, then it will have a negative sign. Also work input will have a negative sign. Hence:
$-50-(-100)=\Delta u$
$\Delta u=50 \mathrm{KJ} / \mathrm{kg}$

Example (3): $(0.3 \mathrm{~kg})$ of nitrogen gas at $\left(40^{\circ} \mathrm{C}\right)$ is contained in a cylinder. The piston is moved to compress nitrogen until the temperature becomes $\left(160{ }^{\circ} \mathrm{C}\right)$. The work done during the process is $(30 \mathrm{~kJ})$. Calculate the heat transferred from the nitrogen to the surroundings. Take ( $\mathrm{C}_{\mathrm{v}}$ for nitrogen $=0.75 \mathrm{~kJ} / \mathrm{kg} . \mathrm{K}$ ).

## Solution:

The absolute temperatures: $T_{1}=40+273=313 K$
$T_{2}=160+273=433 \mathrm{~K}$
Applying the first law of thermodynamics:
$Q-W=\Delta U$
$\Delta U=m C_{v} \Delta T=m C_{v}\left(T_{2}-T_{1}\right)$
$Q-W=m C_{v}\left(T_{2}-T_{1}\right)$
$Q-(-30)=0.3 * 0.75(433-313)$
$Q=-3 K J$

Example (4): An insulated rigid tank initially contains ( 1.5 lbm ) of helium at $\left(80^{\circ} \mathrm{F}\right)$ and ( 50 psia ). A paddlewheel with a work of ( 25.45 Btu ). Determine (a) the final temperature and (b) the final pressure of the helium gas. Take $\left(\mathrm{C}_{\mathrm{v}}=0.753 \mathrm{Btu} / \mathrm{lbm} \cdot{ }^{\circ} \mathrm{F}\right)$

## Solution:

$Q-W=\Delta U$
For insulated $Q=0$
$W=\Delta U=m\left(u_{2}-u_{1}\right)=m C_{v}\left(T_{2}-T_{1}\right)$
$25.45=1.5 * 0.753\left(T_{2}-80\right)$
$T_{2}=102.5^{\circ} \mathrm{F}$
$\frac{P_{1} V_{1}}{T_{1}}=\frac{P_{2} V_{2}}{T_{2}}$
for rigid tank $V_{1}=V_{2}$
$\frac{50}{(80+460)}=\frac{P_{2}}{(102.5+460)}$
$P_{2}=52.1$ psai

## 5. THE FIRST LAW OF THERMODYNAMICS FOR NON-FLOW PROCESSES

The energy equation for non-flow processes is written as:
$Q-W=\Delta U$
$q-w=\Delta u \quad$ (per unit mass)
since $U=m C_{v} T$
$Q-W=m C_{v} \Delta T$
$q-w=C_{v} \Delta T$
(per unit mass)
5.1 Constant Volume (Isochoric) Process: consider a completely closed vessel filled with a perfect gas as shown in the figure below. Let $Q$ units of heat be supplied to the system. This increases the pressure and temperature of the system at constant volume as presented by process $1-2$ on the $(\mathrm{P}-\mathrm{V})$ diagram shown below. Since there is no change in volume, therefore:

Applying the first law of thermodynamics:
$Q-W=\Delta U=m C_{v}\left(T_{2}-T_{1}\right)$
For a constant volume process, no work is done on the system. Hence:
$W=\int P d V=0$
Then: $Q=m C_{v}\left(T_{2}-T_{1}\right)$
For a unit mass, we get:
$q=C_{v}\left(T_{2}-T_{1}\right)$
Example (5): (1 kg) of air enclosed in a rigid container, is initially at (4.8 bar) and (150 $\left.{ }^{\circ} \mathrm{C}\right)$. The container is heated until the temperature becomes $\left(200{ }^{\circ} \mathrm{C}\right)$. Calculate the final pressure of the air and the heat supplied during the process. Take ( $C_{v}=0.718 \mathrm{KJ} / \mathrm{kg} . \mathrm{K}$ )

## Solution:

The absolute temperatures: $T_{1}=150+273=423 \mathrm{~K}$

$$
T_{2}=200+273=473 \mathrm{~K}
$$

Since we have a rigid container, then the volume is constant. $(W=0)$.
For a constant volume process:
$\frac{P_{1}}{T_{1}}=\frac{P_{2}}{T_{2}} \rightarrow \frac{4.8}{423}=\frac{P_{2}}{473}$
$P_{2}=5.37$ bar
$Q=m C_{v}\left(T_{2}-T_{1}\right)=1 * 0.718 *(473-423)$
$Q=35.9 \mathrm{KJ}$
5.2 Constant Pressure (Isobaric) Process: consider a cylinder with a piston carrying perfect gases as shown in the figure below. When heat $(Q)$ is supplied to the system, its temperature will rise and it will expand, forcing the piston to move upward. Thus a displacement work is done by the system against a constant force. The (P-V) diagram of the process is shown in the figure below.

Work done by the system:
$W=\int P d V=P\left(V_{2}-V_{1}\right)$
Applying the first law of thermodynamics:
$Q-W=\Delta U$
then, $\left(U_{2}+P V_{2}\right)-\left(U_{1}+P V_{1}\right)=Q$
since $H=U+P V$
then: $Q=H_{2}-H_{1}$
$Q=m C_{p}\left(T_{2}-T_{1}\right)$
For a unit mass, we get:
$q=C_{p}\left(T_{2}-T_{1}\right)$
It can be seen that during an isobaric process, the heat transfer is equal to the change in enthalpy.

Example (6): When a stationary mass of gas was compressed without friction at constant pressure, its initial state of $\left(0.4 \mathrm{~m}^{3}\right)$ and $(0.105 \mathrm{MPa})$ was found to change to a final state of $\left(0.2 \mathrm{~m}^{3}\right)$ and $(0.105 \mathrm{MPa})$. There was a transfer of $(42.5 \mathrm{~kJ})$ of heat from the gas during the process. How much did the internal energy of the gas change?

## Solution:

Since we have a constant pressure process, then work done by the gas is:
$W=P\left(V_{2}-V_{1}\right)=0.105 \times 10^{6}(0.2-0.4)=-21 K J$
$Q-W=\Delta U$
$-42.5-(-21)=\Delta U$
$\Delta U=-21.5 K J$
